This is a simple modeling question of a river. Given: What water course is this? What country is this? Is this a fresh water or sea water? A: Is the following a standard approach to (non) modeling of a river? Not really. To a first approximation, rivers are always a branch of a larger watercourse. Rivers have an upstream and downstream (water of this river versus the water of that river). They also have one bank and the other bank. A model of the

river could be a model of the larger watercourse, with river as one of the branches. Or it could be a series of discrete modules that model portions of the river. The model may have transitions between the upstream of the river and the downstream of the river. For a very simple model of a river that is easily scalable, you could simply have an upstream and downstream object, each connected to a bank. Then, connect the two banks with a transition. If you wanted to have another river on a different continent in the same region, just create a new branch from the upstream of the original river and its downstream. Add transitions for the new branch, connect them to the bank, and scale the entire model by scaling the river. If you wanted to model the entire world as a single watercourse, you could subdivide the world into a series of sub-models, each with an upstream and downstream, with each sub-model being connected to its neighbor on each side with a transition. Scale each sub-model separately. A: Yes. But there are a few questions to consider. What water course is this? A river. By definition. What country is this? Just like 'What water course is this?' implies that the river is in a country, the country is implied. Is this a fresh water or a1d647c40b
